Phase transition with memory

Gianni Gilardi, Pavia

As is well known, the energy balance for the internal energy and the heat flux yields the standard heat equation, provided that the constitutive law for the heat flux $\mathbf{q}$ is the Fourier law, namely

$$\mathbf{q}(x,t) = \mathbf{q}_0(x) - k_0 \nabla \vartheta(x,t) \tag{1}$$

where ϑ is the temperature and $\mathbf{q}_0$ is known. Let us replace (1) with the law

$$\mathbf{q}(x,t) = \mathbf{q}_0(x) - k_0 \nabla \vartheta(x,t) - \int_0^t k(t-s) \nabla \vartheta(x,s)\, ds \tag{2}$$

which accounts also on the past history of the temperature through the convolution term. Equation (2) is the Coleman–Gurtin or the Gurtin–Pipkin law according to whether k_0 is positive or zero, and leads to an equation whose principal part is parabolic or hyperbolic, respectively, at least when k is a decreasing exponential.

A similar situation happens for phase transition models, like the Stefan problem or the phase field system, when (1) is replaced by (2). In this talk, a brief overview on the results obtained in this field is given, with more detail on some selected problems.
