

# Stability and wall-crossing in algebraic and differential geometry

Jacopo Stoppa  
*Università di Pavia*

STABAGDG  
Brussels, 23<sup>th</sup> April 2012

# 1. Introduction

# General principle

**General principle (after Narasimhan-Seshadri, Atiyah-Bott, Hitchin-Kobayashi, Donaldson, Yau, Tian...)**

Solutions to natural *PDEs* in complex geometry

Natural objects in complex *algebraic* geometry

In terms of families of solutions and objects or *moduli spaces*:

$$\mathcal{M}_{\text{PDE}} \cong \mathcal{M}_{\text{alg}}$$

## General principle

This point of view has been spectacularly successful.

The aim of our project is to **attack a number of open problems which fit in this context.**

At the same time we will **expand this principle** bringing in **new insights and problems coming from recent work in the geometry of quantum field theories.**

Total duration: **4 years.**

## Examples: gauge theory

- **Hermitian Yang-Mills connections:**  $(X, \omega)$  a Kähler manifold (i.e. complex manifold with Riemannian metric which is perfectly adapted to complex structure).

$E \rightarrow X$  holomorphic vector bundle;  $A$  on  $E$  compatible connection  $\Rightarrow$  a complex analogue of usual fields in physical gauge theory.

Field-strength =  $F_A$  = curvature =  $dA + [A, A]$ , 2-form with values in  $\text{ad}(E)$ .

Equation of motion:  $\text{Tr } F_A = \lambda I$ .

### Thm (Hitchin-Kobayashi, Donaldson, Uhlenbeck-Yau)

A solution exists iff  $E$  satisfies a purely algebro-geometric condition, *slope polystability*. This is a constraint on *all the holomorphic subsheaves*.

## Examples: gauge theory

- **Higgs bundles:**  $\Sigma$  a Riemann surface,  $E \rightarrow \Sigma$  rank 2 complex vector bundle with structure group  $SU(2)$ .

$A$  a compatible connection.

$\Phi$  a Higgs field: 1-form with values in  $\text{ad}(E) \otimes \mathbb{C}$ .

Equations of motion are Hitchin's equations:

$$F_A + [\Phi, \Phi^*] = 0$$

$$\bar{\partial}_A \Phi = 0.$$

**Theorem** (Hitchin): solution iff  $(E, \bar{\partial}_A)$  holomorphic,  $(E, \Phi)$  stable.

### (Open) problem (Hitchin, Simpson...):

Understand (hyperkähler) space of solutions  $(\mathcal{M}, g)$  (general gauge groups, singular fields...).

## Examples: Kähler geometry

- **Kähler-Einstein metrics:**  $(X, g)$  Kähler;  $\omega_g$  Kähler differential 2-form.

Ricci form:  $\text{Ric}(\omega_g) = -\partial\bar{\partial} \log \det g_{k\bar{l}}$ .

Einstein's equation in the Kähler world:

$$\text{Ric}(\omega_g) = \lambda \omega_g.$$

Topological constraint:  $c_1(X) = \lambda[\omega_g]$ .

**Aubin-Calabi-Yau Theorem:** If  $c_1(X) \leq 0$  this is the only constraint.

### Kähler-Einstein (open) problem (Calabi, Yau, Tian, Donaldson...)

Solve the equation for positive Ricci curvature. **Main conjecture (Yau-Tian-Donaldson):** this is a purely algebro-geometric problem.

## Examples: Kähler geometry

- **CscK and extremal metrics:** prescribe *scalar curvature* to be constant, or as constant as possible:

Scalar curvature:  $s(g) = -g^{i\bar{j}}\partial_i\bar{\partial}_j \log \det g_{k\bar{l}}$ .

CscK equation and extremal equations:

$$s(g) = \hat{s} = \text{a topological constant.}$$

$$\nabla^{1,0}s(g) = \chi = \text{ess. unique holomorphic vector field.}$$

### CscK (open) problem (Calabi, Yau, Tian, Donaldson...)

Which manifolds have a cscK (or extremal) metric? **Main conjecture (Yau-Tian-Donaldson):** when  $[\omega] = c_1(L)$  for  $L \rightarrow X$  ample, this is a purely algebro-geometric problem.

## 2. Stability and canonical metrics

## K-stability

- **K-(semi, poly)stability:**  $[\omega_g] = c_1(L)$ . Embed  $X \hookrightarrow \mathbb{P}^{N_k}$  using powers  $L^k$ . K-(semi,poly)stability is a constraint on *all* degenerations  $\mathcal{X}$  of  $(X, L)$  induced by flowing under a  $\mathbb{C}^* \curvearrowright \mathbb{P}^{N_k}$ ,  $F(\mathcal{X}) > 0$  ( $\geq 0$ ).

### Theorem (Donaldson)

$\omega_g \in c_1(L)$  cscK  $\Rightarrow (X, L)$  K-semistable.

### Theorem (S.): “blow-up method”

If moreover  $\text{Aut}(X, L)$  discrete  $\Rightarrow$  K-stable. In the extremal case get *relative* K-polystability (with Székelyhidi).

### Conjecture (Yau-Tian-Donaldson)

In general, cscK  $\Leftrightarrow$  K-polystable.

## K-stability: problems and limitations

- **No uniform control:** for analytic purposes need uniform bound on  $F(\mathcal{X})/\|\mathcal{X}\|$ , but it's lacking.
- **Might not be sufficient:** conjectural counterexample by Apostolov, Calderbank, Gauduchon and Tonnesen-Friedman.
- **Not natural:** natural statements like stability  $\Rightarrow$  reductivity, Zariski openness, Atiyah-Bott type theorems on worst degenerations are all *very hard* conjectures.
- **Not compatible with Gromov-Hausdorff limits:** in the approach of Donaldson (also with Chen, ...) Gromov-Hausdorff limits lead to a different notion: **b-stability**.

## Our main objectives

### General objective

**Go beyond K-stability.** Need **much more flexible** notion with respect to natural algebro-geometric operations, but **still necessary for cscK** (extremal). Study its **relation to K-stability** and asymptotic Chow stability.

### Conjecture A and similar problems

Prove naturality properties for our new notion, and a posteriori for K-stability: **equivariance** and **compatibility to maximal tori**, **Zariski openness**, **reductivity** of  $\text{Aut}(X)$ ...

### b-stability

Obtain a detailed understanding of Donaldson's b-stability (the algebraic counterpart of Gromov-Hausdorff limits). **Prove that a cscK manifold is b-stable.**

## Sketch of methodology

### Candidate: stability by filtrations

Encode degenerations by filtrations of  $\bigoplus_k H^0(X, L^k)$ , not necessarily finitely generated (Witt-Nystrom, Székelyhidi). Better behaved, but all the main problems still open. **Bring in methods from birational geometry and the analysis of ample linear series.**

### Variations of the blow-up method

Donaldson made progress on cscK  $\Rightarrow$  b-stable using blow-up method, in the equivariant case. **Develop a non-equivariant version for the blow-up method.**

### Approximation

Develop an **approximation theory for Donaldson's general families** in b-stability by one dimensional objects.

### 3. Hyperkähler metrics and wall-crossing

# Seiberg-Witten and Higgs bundles

- **Seiberg-Witten:** Study  $\mathcal{N} = 2$  Yang-Mills theories on  $\mathbb{R}^3 \times S^1_R \Rightarrow$  a  $\sigma$ -model  $\mathbb{R}^3 \rightarrow$  hyperkähler  $\mathcal{M}$ .
- **Higgs bundles:** Claim  $(\mathcal{M}, g)$  is a moduli space of solutions to  $F_A + R[\Phi, \Phi^*] = \bar{\partial}_A \Phi = 0$ , with prescribed singularities!

Study the **geometry of** moduli of **Higgs bundles**  $(\mathcal{M}, g)$  (especially Hitchin fibration  $\mathcal{M} \rightarrow \mathcal{B}$ ) **via** the structure of  $\mathcal{N} = 2$  **Yang-Mills** (i.e. its operators, spectrum...).

## BPS states and Gaiotto-Moore-Neitzke

- **BPS spectrum:** states in  $\mathcal{N} = 2$  Yang-Mills killed by half the supersymmetry operators.

Find mathematical framework (Donaldson-Thomas theory?):  
Bridgeland, Smith...

- **Wall-crossing:** the number of BPS states is a function  $\Omega(\gamma, u)$  of charge and coupling constant  $u \in \mathcal{B}$ .

$\Omega(\gamma, u)$  jump when  $u$  crosses critical locus: **wall-crossing** formulae as in Joyce-Song, Kontsevich-Soibelman.

### Gaiotto-Moore-Neitzke conjecture(s)

$\Omega(\gamma, u)$  **completely determines**  $(\mathcal{M}, g)$  by (nonperturbative) **instanton corrections** in  $R$  through **integral equation**.

Wall-crossing reflects **continuity** of  $g$ .

# Our main objectives

## General objective

Study the conjecture(s) of Gaiotto-Moore-Neitzke for a large class of  $(\mathcal{M}, g)$ . Prove **existence and uniqueness of solutions** for their integral equation.

## Asymptotic expansion

Study the **convergence of the natural asymptotic expansion** for solution emerging from GMN.

## Additional structures

Study natural additional structures on  $(\mathcal{M}, g)$ : **hyperholomorphic connections**. What is the **mirror** for these constructions?

## Sketch of methodology

### Finite BPS spectra

Concentrate initially on examples where  $\Omega(\gamma, u)$  is **everywhere finite**.

### Comparisons

Establish **precise comparisons** with algebro-geometric work of Joyce and Bridgeland, Toledano-Laredo. Conjecture (S.): asymptotic expansion recovers Joyce's theory (checked in many cases).

### Nahm-type equations

Recast as **infinite dimensional Nahm-type equations**. Bring in recent ideas of Donaldson on infinite dimensional Nahm and geodesics in the space of Kähler potentials.

## 4. The team

- **Jacopo Stoppa** (Università di Pavia and Trinity College, Cambridge) - Principal Investigator. *CscK, K-stability, DT theory, quivers and tropical vertex, GMN theory.*
- **Gabor Székelyhidi** (University of Notre Dame) - Team Member. *CscK and extremal metrics, Monge-Ampère equations, Kahler-Ricci flow, Sasaki geometry.*
- **Two postdocs** (2 + 2 years). With suitable expertise in algebraic or differential geometry.
- **One doctoral student** (3 years). Initially working in low-dimensional examples for b-stability or finite spectrum examples in GMN theory.

## 5. Timeliness and flexibility

**Very active** research areas: recent or forthcoming works of Donaldson (also with Chen, Sun); Bridgeland, Smith...

Forthcoming **Junior Research Trimester** at HIM, Bonn, Sep-Dec 2012 (P.I. will be group leader for “BPS states” group).

Project is **flexible** and can adapt to the area of expertise of highly qualified post-doctoral members.

Good range of **PhD problems** to attract an excellent candidate.
